NRAMP Newsletter for Clinicians, Issue 2, 2016

Welcome to the June issue of our Newsletter for Clinicians. As always, we offer our sincere thanks for your continued and valued support, resulting in referrals, queries, comments and suggestions from around Australia, and at times, from international sources. Your ongoing interest is highly valued and helps us to sustain the workload which is inevitably involved in a study the size of NRAMP. Contents of this Newsletter include achieving 300 consented participants, ongoing recruitment, Conferences at which NRAMP will be represented this year and next, and a look at participants who have consented to take part in NRAMP on more than one occasion.

We are delighted to report that we have, this month, achieved 300 consented participants in to NRAMP. This represents several years of work by the NRAMP Team and acknowledges the importance of your ongoing referrals. Although 30 participants are still current and data entry continues, we now have the opportunity to conduct indepth analyses from our rich database. In so doing, we will gain insight in to specific areas which require further work, areas on which to focus for the future, and the opportunity to fine-tune models of care to support robust maternal and infant outcomes in the future.

NRAMP Recruitment beyond 300 participants

So what happens next? We envisage recruitment to continue, not only for pregnant women with mental illness who take antipsychotic medication during pregnancy but also for pregnant women with mental illness who do not take these medications during pregnancy. The latter will provide us with a much-needed ‘Control Group’, adding further robust information to our current dataset and strengthening our position of support for women in this vulnerable population. It has been a long road to this point, but the potential benefits to the community we serve are innumerable and more than worth the effort. We therefore encourage your ongoing referrals and thank you in advance for your continued interest.

‘In Her Shoes’ Conference in 2016

On Saturday 3rd September, the Women’s Mental Health Team, which is part of the Monash Alfred Psychiatry research centre (MAPrc), Alfred Hospital and Monash University, will be presenting the second ‘In Her Shoes’ Conference, a one day event to be held at the Stamford Plaza in Melbourne. The Conference will focus on women’s mental health across the lifespan, and will include mental health and young women, mental health and motherhood, perimenopause and violence against women. Case scenarios will be discussed, along with opportunities for delegates to share clinical cases from the floor. GPs are invited to attend, with the event being sponsored by Servier Australia, as in 2015. All enquiries regarding this event should be addressed to Servier Australia, by phone: (03) 8823 7333 or email: info@au.netgrs.com We highly recommend this Conference to you and look forward to seeing you there.

World Congress on Women’s Mental Health in 2017

NRAMP will also be represented at the World Congress on Women’s Mental Health, to be held in Dublin in March 2017, which provides further opportunity to collaborate with global research groups and expand our reach in the community. There is always much interest in our work at these forums, which amongst other things, confirms the overall lack of available information on antipsychotic medication safety in pregnancy.
NRAMP Snapshots

Multiple consenters to NRAMP

One of the many things that makes NRAMP unique is the group of women who have consented to take part in the study on more than one occasion. To date, we have 25 women in this group, one of whom has consented four times and another who has consented three times, bringing the total consents to 53.

Demographic data

Participant ages ranged from 27 to 42 years, with the mean age being 33 years. Thirty eight women were married, while 16 were living in de-facto relationships. Bipolar affective disorder was heavily represented in this group, being recorded for 35/53 (66%) women. Other mental illness diagnoses included schizophrenia (8), schizoaffective disorder (6) and depression (5).

The majority of women lived in Victoria (24), with 16 in NSW and 8 in WA. Fourteen women worked full time, 18 worked part time and 18 were unemployed during pregnancy. Women tended to be well educated, with 28 completing post-graduate education and 14 completing tertiary education. Interestingly, the majority of women, 47/53 (89%) did not smoke during pregnancy, likewise, 46/53 (87%) of women did not consume alcohol during pregnancy and none used illicit drugs during pregnancy. Our data report that the majority of women in this group appear to be well-educated, highly motivated, very employable and living in stable relationships.

Maternal outcomes

NRAMP collects maternal weight and Body Mass Index (BMI) data from pre-pregnancy to 12 months postnatal. In this current group, we found some interesting results. We recorded pre-pregnancy overweight BMIs (26-30) for 9 women, obese BMIs (31-40) for 13 women and morbidly obese BMIs (>40) for 3 women. These outcomes have been charted against their respective maternal antipsychotic, which clearly indicate the weight-promoting properties of quetiapine (17/53), being more significant than olanzapine data (3/53) in this group. Furthermore, weight gain of >15kg during pregnancy was recorded for 23/53 (47%) of women, with gains of 16-36kg overall. Even though there was also a family history of diabetes for 34/53 women (64%), only 8/53 (15%) developed gestational diabetes (GDM), with one report of ongoing diabetes at 12 months postnatal. This is a lesser number when compared with the overall NRAMP GDM outcome of 62/300 (21%), which is significant in light of the Australian Institute of Health and Welfare (AIHW, 2012) figure of 5-10% in the general Australian population.

Birth outcomes

We recorded 47/53 live births, including one set of twins, three stillbirths, two miscarriages and one termination. (1) Stillbirth at 33/40 weeks, post mortem indicated intrauterine fetal hypoxia but was otherwise normal (maternal quetiapine). (2) Stillbirth at 31/40 weeks, post mortem indicated hypovolaemia, anaemia, with feto-maternal transfusion (maternal quetiapine). (3) Stillbirth at 28/40 weeks, Trisomy 18 (Edward’s Syndrome) (maternal olanzapine). (2) Stillbirth at 33/40 weeks, post mortem indicated intrauterine fetal hypoxia but was otherwise normal (maternal quetiapine).

Premature births (< 37/40 weeks) number 7/47 (15%); overall NRAMP data reports 38/300 (13%), compared with 9% in the general Australian population (AIHW, 2012). Neonatal respiratory distress was reported in 16/47 (34%) infants (overall NRAMP data reports 86/300 (29%), compared with 20% in the general Australian population (AIHW, 2012). Mediation withdrawal symptoms were noted in 11/47 (23%) infants (overall NRAMP data reports 57/300 (19%), however the AIHW do not provide any current data with which to compare our outcomes). Neonatal Intensive Care Unit (NICU) or Special Care Nursery (SCN) admissions, or both, totalled 18/47 (38%). Overall NRAMP data reports 101/300 (34%), compared with 15% in the general Australian population data (AIHW, 2012).

Discussion

Overall NRAMP outcomes clearly indicate that women in our cohort are representative of pregnant women with mental illness in our communities, albeit women who are generally well-educated and able to look after themselves and their families. The significance of our findings should continue to encourage the support of good perinatal physical and mental health. Women need to be educated about healthy lifestyle practices and empowered to make educated decisions, with the support of their clinicians, on safe medication management, including antipsychotic medication in pregnancy and breastfeeding.
